

Ant Colony Optimization Algorithms for Dynamic Optimization: A Case Study of the Dynamic Travelling Salesperson Problem – Supplementary Material

Michalis Mavrovouniotis, Shengxiang Yang, Mien Van, Changhe Li, and Marios Polycarpou

IV. EXPERIMENTAL SETUP

A. Dynamic Test Cases

TSP instances were obtained from the TSPLIB benchmark library [1], which is available at <http://comopt.ifl.uni-heidelberg.de/software/TSPLIB95/>, to generate dynamic test cases as described in Section II of the paper. Specifically, the frequency of change was set proportionally to the size of the problem instance as follows: $f = 2.5n$ and $f = 25n$, indicating quickly (e.g., before the algorithm converges, denoted as `fast`) and slowly (e.g., after the algorithm has converged, denoted as `slow`) changing environments, respectively. Note that the resulting f value is rounded up (if needed), so that the dynamic change will occur at the start or the end of the algorithmic iteration. The magnitude of change was set to $m = 0.1$, $m = 0.25$, $m = 0.5$, and $m = 0.75$, indicating small, to medium, to large dynamic changes, respectively. The dynamic settings for each DTSP test case are selected to systematically analyze the dynamic behavior of ACO algorithms (i.e., their ability to recover fast and produce the best output). Note that usually as the frequency of change is faster and the magnitude of change is increasing the DTSP test case becomes harder to address [2], [3].

B. Parameter Settings

The common parameters of all ACO algorithms were set to typical values as follows [4]: $\alpha = 1$ and $\beta = 5$ (for all the experiments). The colony size ω for each framework was investigated for the two types of DTSPs separately with values $\omega = \{50, 25, 10, 5\}$. In addition, the key parameter of the evaporation-based framework variants (i.e., the evaporation rate ρ) was investigated with values $\rho = \{0.1, 0.2, 0.5, 0.8\}$ and the key parameter of the population-based framework variants (i.e., the population-list size K) was investigated with values $K = \{2, 3, 5, 10\}$. The replacement ratio r_i of the generated immigrants for RIACO, EIACO, HIACO, HIACO-II, MIACO and EIIACO was investigated with values $r_i = \{0.1, 0.5, 0.8\}$. For $\mathcal{M}\mathcal{M}\mathcal{A}\mathcal{S}_S$ the number of discrete rate values available to the self-adaptive evaporation mechanism was investigated with values ranging from 5 to 50. For $\mathcal{M}\mathcal{M}\mathcal{A}\mathcal{S}_{caste}$, one caste uses the random proportional decision rule while the other uses the pseudorandom proportional decision rule, and MC- $\mathcal{M}\mathcal{M}\mathcal{A}\mathcal{S}$ uses two independent colonies.

The combination of these parameters that were found to yield reasonable performance is $\omega = 5$ for most DTSPs with node changes and $\omega = 25$ for most DTSPs with weight changes for all ACO algorithms. Furthermore, for both DTSPs with node and weight changes the remaining parameters are $\rho = 0.8$, $K = 3$, $r_i = 0.5$ and 20 discrete rate values for ACO algorithms using these parameters.

For each ACO algorithm on each DTSP test case, 30 independent runs were executed on the same set of random seed numbers. For each run, 100 environmental changes were allowed and the value of the best-so-far ant since the last change of the environment was recorded.

Bold values indicate statistical significance

B. Effect of Main Framework Features

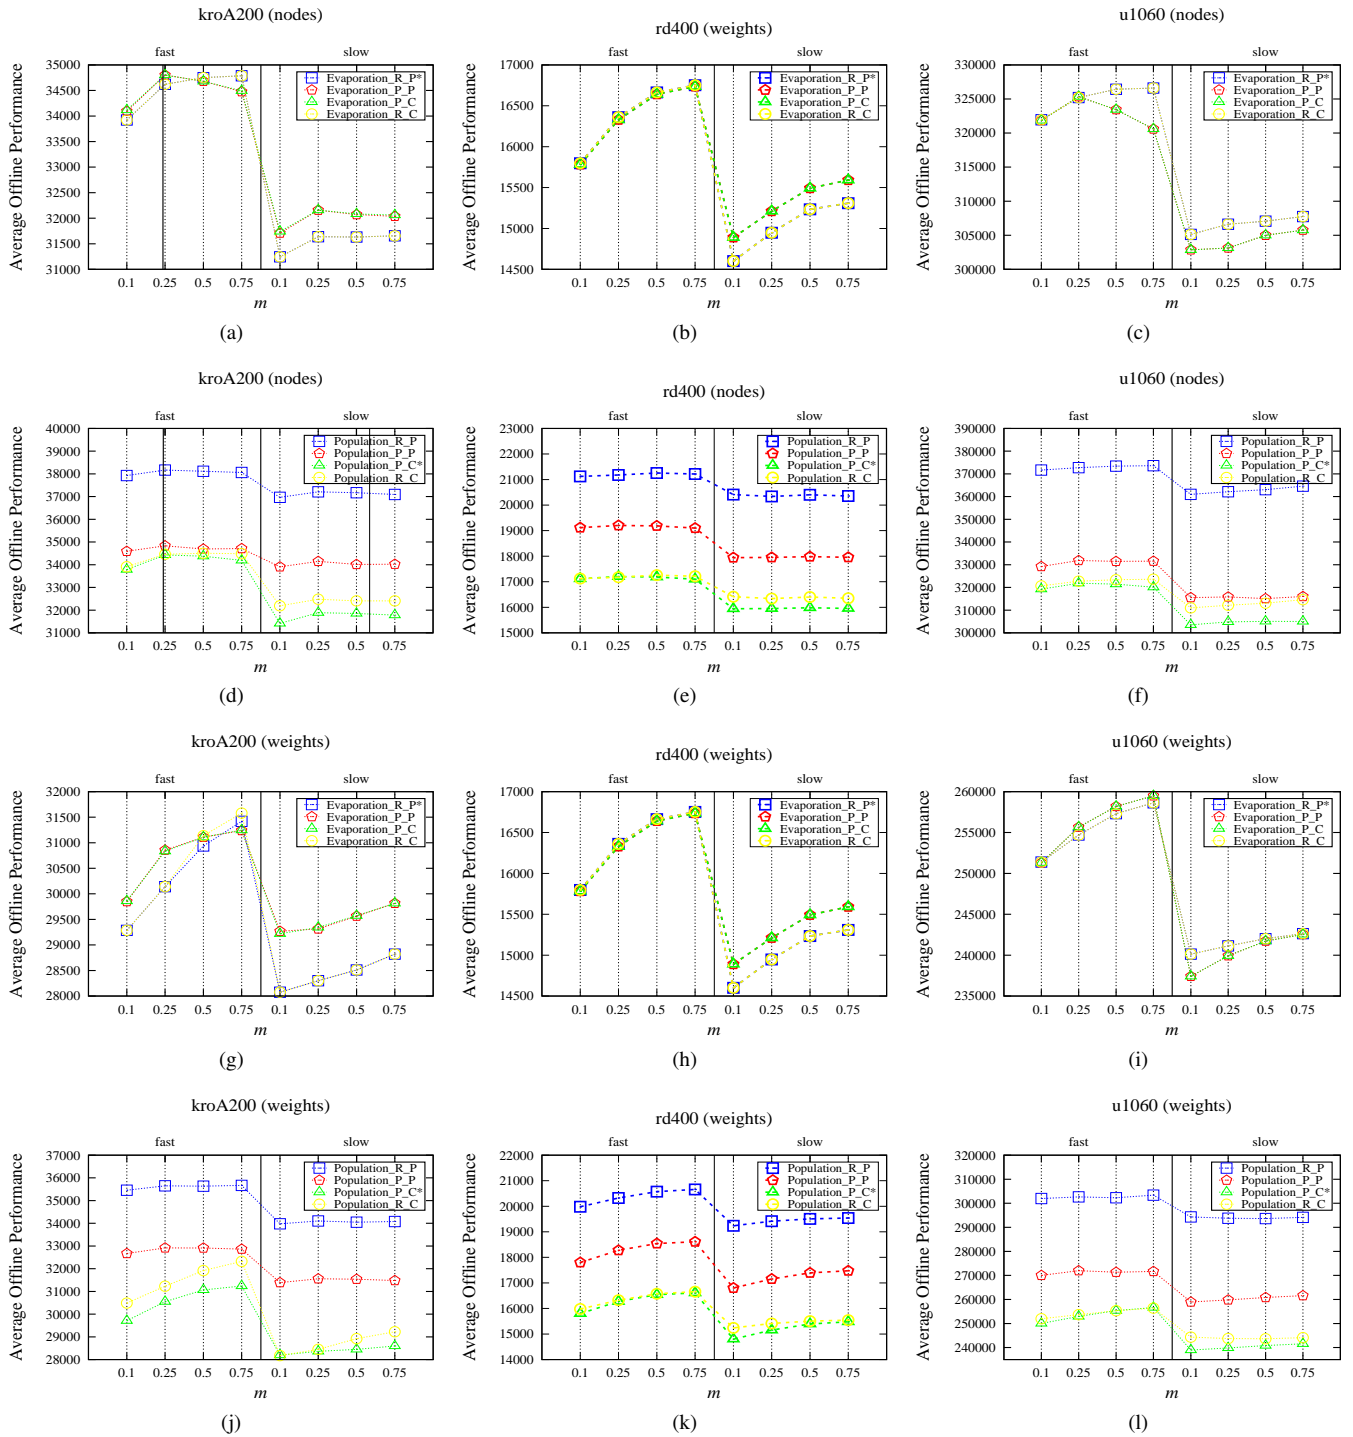

Fig. 3: Averaged (over 30 runs) offline performance for evaporation-based (a)(b)(c)(g)(h)(i) and population-based (d)(e)(f)(j)(k)(l) frameworks with alternative decision rules and pheromone update policies for different DTSPs. *These combinations are the default ones.

C. Effect of Dynamic Strategies

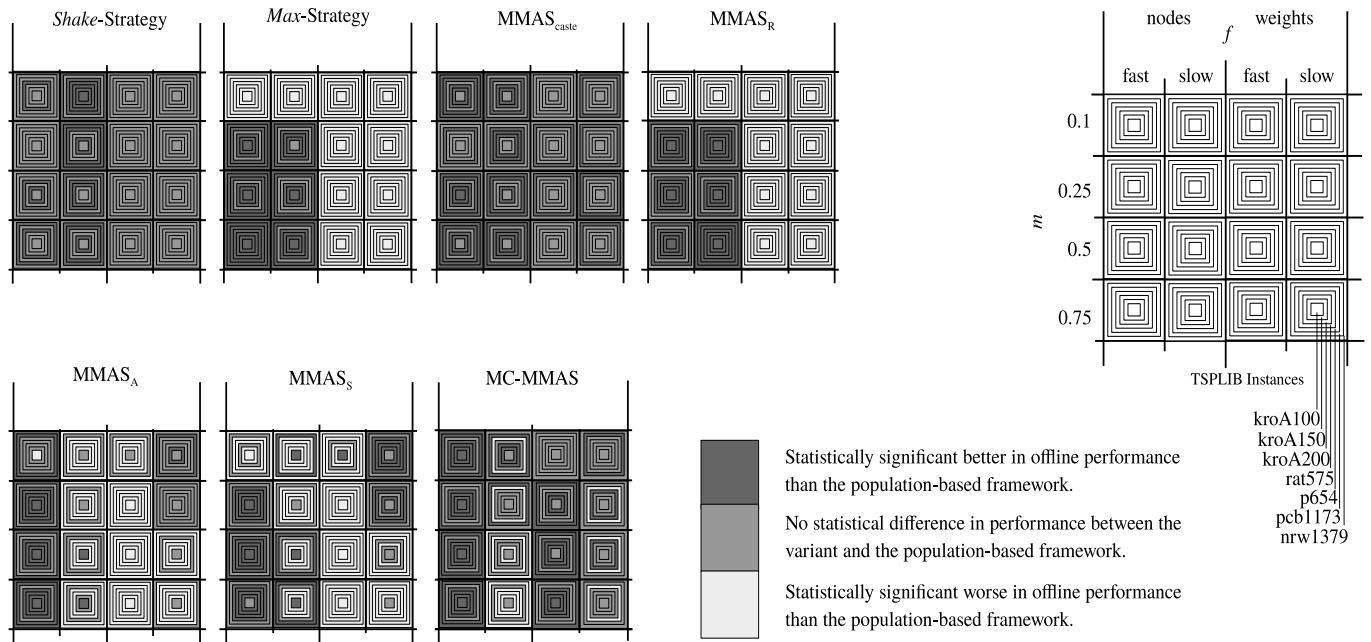

Fig. 4: Each square represents the comparisons of the statistical tests of the aforementioned ACO variant against the evaporation-based framework. Each square is subdivided into sixteen smaller squares that represent the dynamic settings of the DTSP. The squares are grouped by the type of change. Each smaller square contains a stack of increasingly larger boxes that represents a set of increasingly larger problem instances.

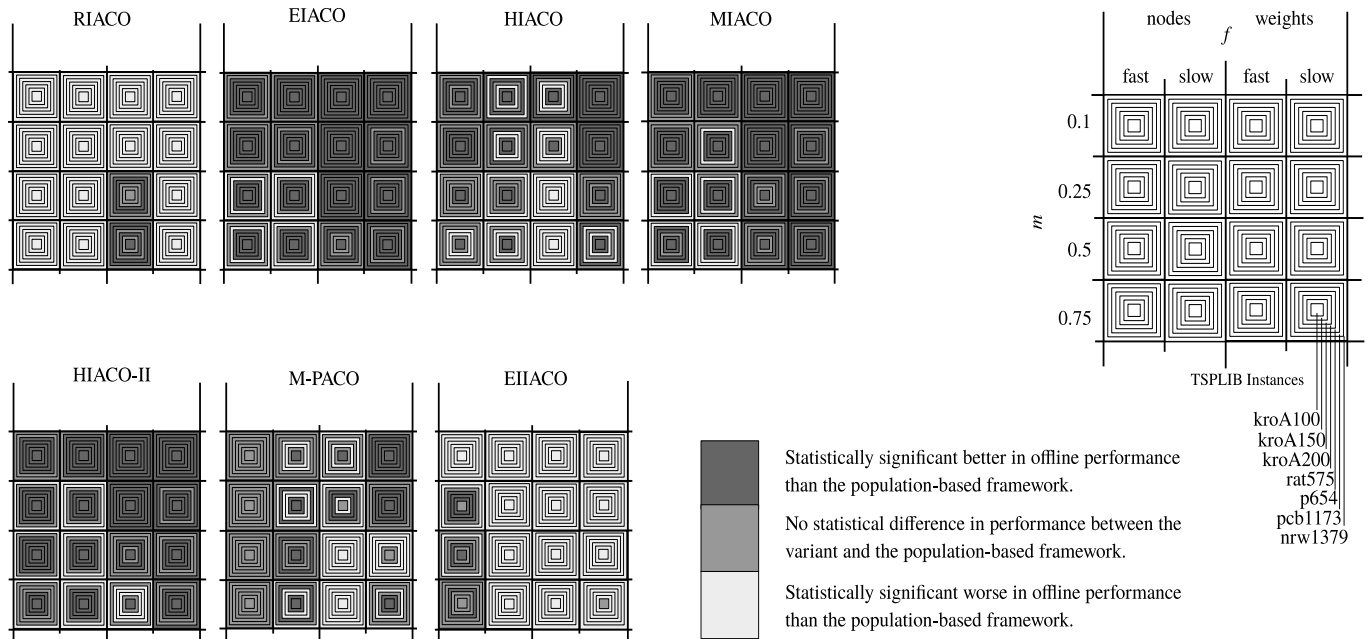

Fig. 5: Each square represents the comparisons of the statistical tests of the aforementioned ACO variant against the population-based framework. Each square is subdivided into sixteen smaller squares that represent the dynamic settings of the DTSP. The squares are grouped by the type of change. Each smaller square contains a stack of increasingly larger boxes that represents a set of increasingly larger problem instances.

D. Effect of Utilizing Change-Related Information

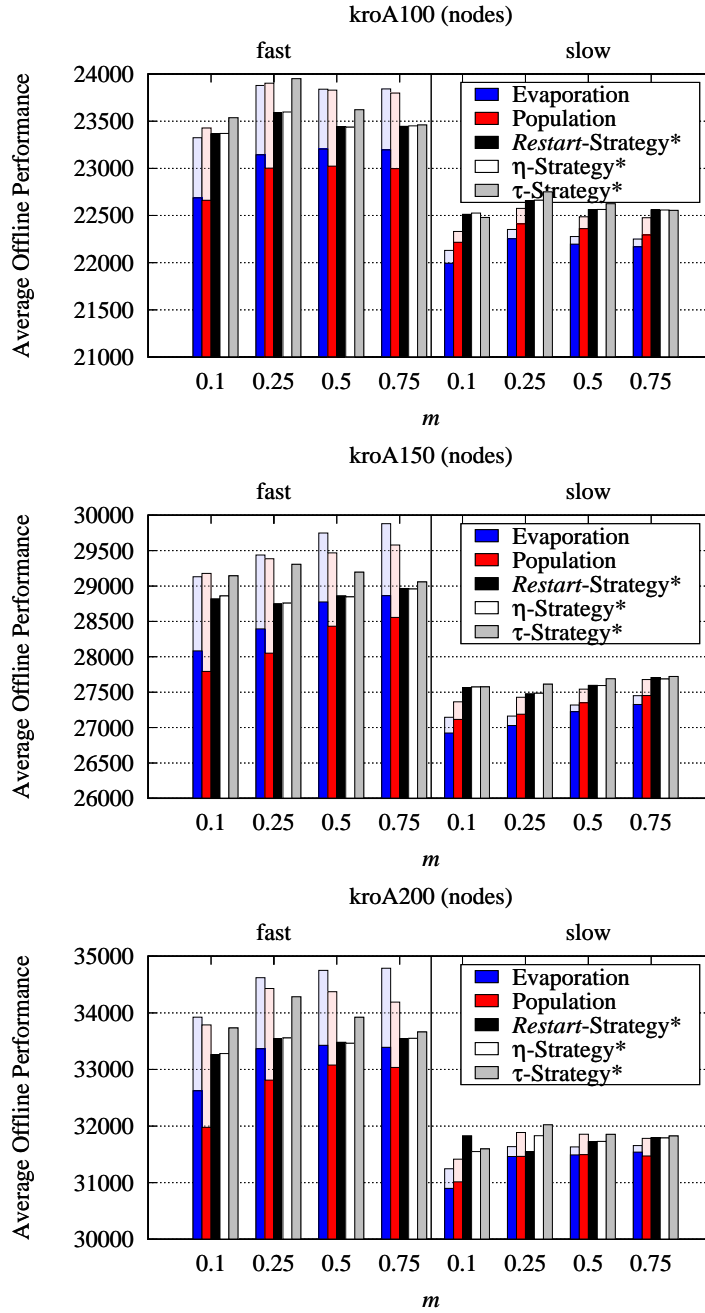

Fig. 6: [Note that Fig. 6 here, is Fig. 4 on the paper] $\bar{P}_{offline}$ (averaged over 30 runs) results of evaporation-based and population-based frameworks, and three evaporation-based variants when utilizing change-related information for DTSPs with node changes. Each bar is divided into two parts that represent the results when utilizing change-related information (darker) or not (lighter). *These strategies have been designed to utilize change-related information and, thus, the values when information is not utilized do not exist.

E. Comparisons with Evolutionary Algorithms

TABLE IV: Experimental results regarding the $\bar{P}_{offline}$ (averaged over 30 runs) of ACO algorithms with state-of-the-art evolutionary algorithms for DTSPs with weight changes with $f = n \cdot 100$ and m randomly chosen from a uniform distribution in $(0.0, 0.5]$.
